Question 1 - PAC learning analysis

Consider the Boolean data set posted in MyCourses named q1.csv. We may choose to model this as an arbitrary Boolean function f(x1..xn)=y. If we do so, we can use PAC learning to predict the expected accuracy of our model. Answer the following questions in your write up. Show your work.

- a) How many different hypotheses are there (give an exact number or numeric expression)? **Answer**: There are 2 classes and 6 variables, so totally there are 2^{2^6} different hypotheses.
- b) With what probability can we guarantee a classifier that is 90% accurate (i.e with no more than 10% classification error)? How about one that is 80% accurate?

Answer:

90% accurate:

H =
$$2^{2^6}$$
 = 18446744073709551616 , $\epsilon = 1-0.9 = 0.1$, N = 200 $\sigma = H*(1-\epsilon)^N \approx 13014323873$ $1-\sigma \leq 0$

So there is no possible to guarantee the classifier has a 90% accurate.

80% accurate:

H =
$$2^{2^6}$$
 = 18446744073709551616 , $\epsilon = 1-0.8=0.2$, N = 200 $\sigma = H*(1-\epsilon)^N\approx 0.765$
1 - $\sigma = 0.235$

So there is 23.5% possible to guarantee the classifier has a 80% accurate.

c) How many additional samples would we want to get a classifier with 90% accuracy, 80% of the time?

Answer:

$$1-\sigma=0.8$$
 , $\sigma=0.2$, $\epsilon=1-0.9=0.1$ M $\geq \frac{1}{\epsilon}(\ln|H|+\ln\frac{1}{\sigma})\approx 456$ 456 – 200 = 256

So we should have additional 256 samples.

d)

Answer:

H =
$$3^6$$
 = 729
$$1-\sigma=0.8 \ \ , \sigma=0.2 \ \ , \ \ \epsilon=1-0.9=0.1$$

$$M \geq \frac{1}{\epsilon}(\ln |H| + \ln \frac{1}{\sigma}) \ \approx 81.9$$
 So we should have at least 82 samples.

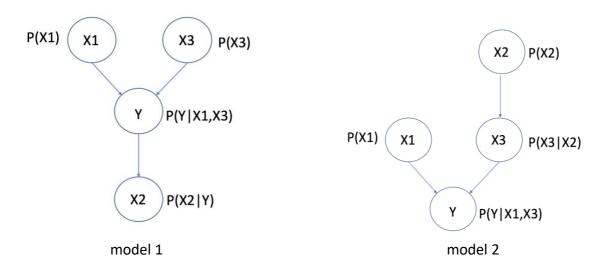

Question 2 - Bayes nets

Consider a problem with four Boolean variables (one of which is the class we are trying to predict). Here are two different sets of assumptions about how the variables are related:

For each set of assumptions:

a) Draw the corresponding Bayes network, including the symbolic parameters that are required for a full representation of the problem.

Answer:

b) Write an exact symbolic expression for $P(Y=True \mid x1=True \land x2=False \land x3=True)$, using only the parameters of the model.

Answer:

Model 1:

$$\begin{split} & = \frac{\mathsf{P}(\mathsf{Y} \! = \! \mathsf{T} \mid \mathsf{X} 1 \! = \! \mathsf{T}, \, \mathsf{X} 2 \! = \! \mathsf{F}, \, \mathsf{X} 3 \! = \! \mathsf{T})}{\mathsf{P}(\mathsf{X} 1 \! = \! \mathsf{T}, \, \, \mathsf{X} 2 \! = \! \mathsf{F}, \, \, \mathsf{X} 3 \! = \! \mathsf{T})} \\ & = \frac{\mathsf{P}(\mathsf{X} 1 \! = \! \mathsf{T}, \, \, \mathsf{X} 2 \! = \! \mathsf{F}, \, \, \mathsf{X} 3 \! = \! \mathsf{T})}{\mathsf{P}(\mathsf{X} 1 \! = \! \mathsf{T}, \, \, \mathsf{Y} 2 \! = \! \mathsf{F}, \, \, \mathsf{X} 3 \! = \! \mathsf{T})} \\ & = \frac{\mathsf{P}(\mathsf{X} 1 \! = \! \mathsf{T}, \, \mathsf{P}(\mathsf{X} 3 \! = \! \mathsf{T}) \mathsf{P}(\mathsf{Y} 2 \! = \! \mathsf{F}, \, \mathsf{Y} 3 \! = \! \mathsf{T}) \mathsf{P}(\mathsf{X} 2 \! = \! \mathsf{F}, \, \mathsf{Y} 3 \! = \! \mathsf{T}) \mathsf{P}(\mathsf{X} 2 \! = \! \mathsf{F}, \, \mathsf{Y} 3 \! = \! \mathsf{T}) \mathsf{P}(\mathsf{X} 2 \! = \! \mathsf{F}, \, \mathsf{Y} 3 \! = \! \mathsf{T}) \mathsf{P}(\mathsf{X} 2 \! = \! \mathsf{F}, \, \mathsf{Y} 3 \! = \! \mathsf{T}) \mathsf{P}(\mathsf{X} 2 \! = \! \mathsf{F}, \, \mathsf{Y} 3 \! = \! \mathsf{T}) \mathsf{P}(\mathsf{X} 2 \! = \! \mathsf{F}, \, \mathsf{Y} 3 \! = \! \mathsf{T}) \mathsf{P}(\mathsf{X} 2 \! = \! \mathsf{F}, \, \mathsf{Y} 3 \! = \! \mathsf{T}) \mathsf{P}(\mathsf{X} 2 \! = \! \mathsf{F}, \, \mathsf{Y} 3 \! = \! \mathsf{T}) \mathsf{P}(\mathsf{X} 2 \! = \! \mathsf{F}, \, \mathsf{Y} 3 \! = \! \mathsf{T}) \mathsf{P}(\mathsf{X} 2 \! = \! \mathsf{F}, \, \mathsf{Y} 3 \! = \! \mathsf{T}) \mathsf{P}(\mathsf{X} 2 \! = \! \mathsf{F}, \, \mathsf{Y} 3 \! = \! \mathsf{T}) \mathsf{P}(\mathsf{X} 2 \! = \! \mathsf{F}, \, \mathsf{Y} 3 \! = \! \mathsf{T}) \mathsf{P}(\mathsf{X} 2 \! = \! \mathsf{F}, \, \mathsf{Y} 3 \! = \! \mathsf{T}) \mathsf{P}(\mathsf{X} 3 \! = \! \mathsf{T}, \, \mathsf{Y} 3 \! = \! \mathsf{T}) \mathsf{P}(\mathsf{X} 3 \! = \! \mathsf{T}, \, \mathsf{Y} 3 \! = \! \mathsf{T}, \, \mathsf{Y} 3 \! = \! \mathsf{T}, \, \mathsf{Y} 3 \! = \! \mathsf{T}) \mathsf{P}(\mathsf{Y}, \, \mathsf{Y}, \, \mathsf$$

Model 2:

$$\begin{split} & = \frac{\mathsf{P}(\mathsf{Y} \! = \! \mathsf{T} \mid \mathsf{X} 1 \! = \! \mathsf{T}, \; \mathsf{X} 2 \! = \! \mathsf{F}, \; \mathsf{X} 3 \! = \! \mathsf{T})}{\mathsf{P}(\mathsf{X} 1 \! = \! \mathsf{T}, \; \mathsf{X} 2 \! = \! \mathsf{F}, \; \mathsf{X} 3 \! = \! \mathsf{T})} \\ & = \frac{\mathsf{P}(\mathsf{X} 1 \! = \! \mathsf{T}, \; \mathsf{X} 2 \! = \! \mathsf{F}, \; \mathsf{X} 3 \! = \! \mathsf{T})}{\mathsf{P}(\mathsf{X} 1 \! = \! \mathsf{T}) \mathsf{P}(\mathsf{X} 2 \! = \! \mathsf{F}) \mathsf{P}(\mathsf{X} 3 \! = \! \mathsf{T} | \mathsf{X} 2 \! = \! \mathsf{F}) \mathsf{P}(\mathsf{Y} \! = \! \mathsf{T} | \mathsf{X} 1 \! = \! \mathsf{T}, \; \mathsf{X} 3 \! = \! \mathsf{T})}{\mathsf{\Sigma}_{\mathsf{Y} = (T,F)} \, \mathsf{P}(\mathsf{X} 1 \! = \! \mathsf{T}) \mathsf{P}(\mathsf{X} 2 \! = \! \mathsf{F}) \mathsf{P}(\mathsf{X} 3 \! = \! \mathsf{T} | \mathsf{X} 2 \! = \! \mathsf{F}) \mathsf{P}(\mathsf{Y} \! = \! \mathsf{T} | \mathsf{X} 1 \! = \! \mathsf{T}, \; \mathsf{X} 3 \! = \! \mathsf{T})} \end{split}$$

c) Based on these data points, compute the maximum-likelihood values for the parameters needed by each network.

Answer:

Model 1:

P(X1=T) = 0.315 P(X1=F) = 0.685 P(X3=T) = 0.595 P(X3=F) = 0.405

P(Y=T | X1=T,X3=T) = 0.079 P(Y=F | X1=T,X3=T) = 0.921 P(Y=T | X1=T,X3=F) = 0.440 P(Y=F | X1=T,X3=F) = 0.560 P(Y=T | X1=F,X3=T) = 0.889 P(Y=F | X1=F,X3=T) = 0.111 P(Y=T | X1=F,X3=F) = 0.142 P(Y=F | X1=F,X3=F) = 0.857

P(X2=T | Y=T) = 0.755 P(X2=F | Y=T) = 0.245 P(X2=T | Y=F) = 0.207 P(X2=T | Y=F) = 0.792

Model 2:

P(X1=T) = 0.315 P(X1=F) = 0.685 P(X2=T) = 0.465 P(X2=F) = 0.535

P(X3=T | X2=T) = 0.677 P(X3=F | X2=T) = 0.323 P(X3=T | X2=F) = 0.523 P(X3=T | X2=F) = 0.477

P(Y=T | X1=T,X3=T) = 0.079 P(Y=F | X1=T,X3=T) = 0.921 P(Y=T | X1=T,X3=F) = 0.440 P(Y=F | X1=T,X3=F) = 0.560 P(Y=T | X1=F,X3=T) = 0.889 P(Y=F | X1=F,X3=T) = 0.111 P(Y=T | X1=F,X3=F) = 0.142 P(Y=F | X1=F,X3=F) = 0.857

d) For each network, two variables are specified as independent (i.e. with no incoming edges). Is this assumption supported by the data in each case?

Answer:

Model 1:

P(X1=T) = 0.315 P(X3=T) = 0.595

P(X1=T, X3=T) = 38/200 = 0.19 = P(X1=T)* P(X3=T)

So in model 1, X1 and X3 are independent.

Model 2:

P(X1=T) = 0.315 P(X2=T) = 0.465

 $P(X1=T, X2=T) = 46/200 = 0.23 \neq P(X1=T)*P(X2=T)$

So in model 1, X1 and X3 are not independent.

Question 3 - Learning and inference in Naive Bayes.

The data set given in q3.csv is synthetically generated, but labeled in an intentional way. Note that it includes both discrete and real-valued parameters. Use the Naive Bayes model for the data, with Spam being the parent class, and also assume that each real-valued parameter has a Gaussian distribution.

a) Using the data in q3.csv, compute the maximum-likelihood parameters for this network.

```
P(in html=False| is spam=False) = 0.41304347826086957
P(in html=True| is spam=False) = 0.5869565217391304
P( has emoji=False| is spam=False) = 0.8526570048309179
P( has emoji=True| is spam=False) = 0.1473429951690821
P( sent to list=False| is spam=False) = 0.6884057971014492
P( sent to list=True| is spam=False) = 0.3115942028985508
P( from .com=False| is spam=False) = 0.7246376811594203
P( from .com=True| is spam=False) = 0.2753623188405797
P( has my name=False| is spam=False) = 0.39855072463768115
P( has my name=True| is spam=False) = 0.6014492753623188
P( has sig=False| is spam=False) = 0.6763285024154589
P( has sig=True| is spam=False) = 0.32367149758454106
P( # sentences) = mean:6.190821256038648, var:6.400785315876683
P( # words) = mean:70.77053140096618, var:912.7661847417676
```

```
P(in html=False| is spam=True) = 0.2441860465116279
P(in html=True| is spam=True) = 0.7558139534883721
P( has emoji=False| is spam=True) = 0.8023255813953488
P( has emoji=True| is spam=True) = 0.19767441860465118
P( sent to list=False| is spam=True) = 0.9302325581395349
P( sent to list=True| is spam=True) = 0.06976744186046513
P( from .com=False| is spam=True) = 0.2558139534883721
P( from .com=True| is spam=True) = 0.7441860465116279
P( has my name=False| is spam=True) = 0.6511627906976745
P( has my name=True| is spam=True) = 0.34883720930232553
P( has sig=False| is spam=True) = 0.3372093023255814
P( has sig=True| is spam=True) = 0.6627906976744187
P( # sentences) = mean:3.9767441860465116, var:3.7203893996754998
P( # words) = mean:68.83720930232558, var:79.34559221200648
```

b) For each row of the file q3b.csv, use the values of the features other than Spam to compute P(Y | feature values) for each row. Compute an overall classification error rate based on a threshold P(Y) of 0.5.

classification error rate:15.5%

c) Playtime! Repeat the preceding analysis, but ignoring some or all of the features (columns), and compare the classification accuracy. Choose a subset of the features that is small but seems to give good results.

I just try each possible from 1 to 7 parameter from front to end and calculate each error rate. Then when I have 1 parameter, I get the error rate is 20%, or when 5 parameters, the error rate is 27.5%.
